

AXPA7851Q

4 x 48W MOSFET
Quad Bridge Power Amplifier

Datasheet — Dec 2022

Description

AXPA7851Q is an automotive AEC-Q100 certified quad bridge class AB car radio audio power amplifier designed in BCD (Bipolar, CMOS, DMOS) technology with a fully complementary P-Channel/N-Channel output structure. It has a rail to rail output voltage swing, high output current and low saturation losses, giving it an excellent distortion performance. AXPA7851Q can operate down to 6V for low voltage operation to achieve 'start-stop' battery profile during engine stop enabling reduction in overall emissions.

Features

- Automotive AEC-Q100 Certified 
- Multipower BCD technology with DMOS MOSFET output power stage
- Hi-Fi class low distortion
- Low output noise
- High immunity to RF noise injection
- Standby function
- Mute function
- Auto-mute at min. supply voltage detection
- Low external component count
 - No external compensation
 - No bootstrap capacitors
- Internally fixed gain (26dB)
- Capable to operate down to 6V (e.g. “start-stop”)
- High output power capability:
 - 4 x 48W/4Ω Max.
 - 4 x 28W/4Ω @ 14.4V, 1kHz, 10%
- Protections:
 - Output short circuit to GND, to Vs, across the load
 - Very inductive loads
 - Overrating chip temperature with soft thermal limiter
 - Output DC Offset detection
 - Output Clipping detection
 - Load dump
 - ESD

CDTHD	Clip detector THD level	Vs > 6.5V	-	2	-	%

4 Functional Description

4.1 Overview

AXPA7851Q is a complementary quad audio power amplifier designed in BCD Technology and it is automotive AEC-Q100 certified. Integrated within the AXPA7851Q are:

- 4 dependent class AB amplifiers with DMOS Mosfet output stages
- Clipping detector
- Offset Detection circuit with CDOD pin
- Standby function with STBY pin
- Mute function with MUTE pin
- Circuits fully operational down to 6V, with no pop noise and uninterrupted play during battery transitions.
- Protection circuits for
 - short circuit
 - open circuit
 - over voltage
 - over temperature

It is available in package FZIP25.

4.2 Inputs

AXPA7851Q's channel inputs are ground-compatible with reference to ACGND. Referring to application circuit (Figure 2), input capacitors of 0.47 μ F will attain a low frequency cut-off of around 16Hz. For best pop noise minimization, input capacitors should be 1/4 of the capacitor connected to ACGND pin.

4.3 Standby and Mute

Standby and Mute functions are controlled by CMOS compatible STBY and MUTE pins.

Control signals for these functions should be coupled to AXPA7851Q using a RC circuit (refer to Figure 2 Application Diagram) to damp any sharp transition, preventing unwanted audible transient noise. If not used, an external resistive pull up to V_s should be connected.

4.4 SVR – Supply Voltage Rejection

The SVR pin is set internally to $V_s/4$ and serves as the input voltage reference as well as to generate the $V_s/2$ output reference.

An external capacitor connected to the SVR help in supply voltage ripple rejection and serves 3 functions:

1. Start-up time
2. Shut-down time
3. Pop noise free transitions.

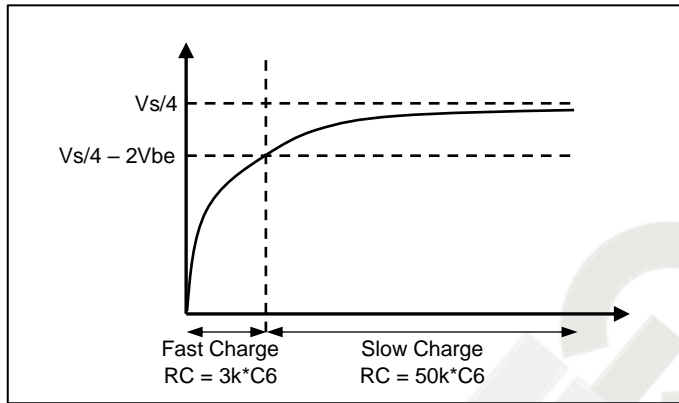

A minimum capacitance value of 10 μ F is recommended.

Upon STBY going beyond the 2.6V threshold, the SVR pin is charged for normal operation.

The Start-up profile time constant is determined by an internal R coupled with the external capacitor. A 2-step profile is designed with a fast charge of 3k Ω from 0 to $V_s/4-2V_{be}$ voltage and thereafter a slower charge through 50k Ω to $V_s/4$ voltage.

A time constant slower than 2.5V/ms is recommended for pop-free transitions.

Figure 4 SVR charge diagram

Proper sequencing of the MUTE and STBY can ensure no audible noise during transition. Placing the amplifier in Mute prior to the device going into or coming out from Standby will ensure no audible noise in the transition.

4.5 Operation Modes

4.5.1 Low Voltage Operation

In the effort to reduce emissions of polluting substances, OEM specifications dictate that the car engine automatically stops when the car is stopping at traffic lights. AXPA7851Q can meet this operation requirement.

It provides for continuous operation when the battery falls as low as 6V, remaining fully operational. The output power is however reduced accordingly to the available voltage supply. Upon battery voltage dropping below 6V, a proper sequencing is performed with amplifier first muted and then the SVR capacitor discharged. On returning to above 6V, the amplifier restarts.

4.5.2 Cranks

AXPA7851Q has excellent performance on worst case cranks profile from 16V to 6V, continuing to play and without producing any pop noise. It can sustain operation for battery cranking curves shown below:

Figure 5 Battery cranking curve example 1

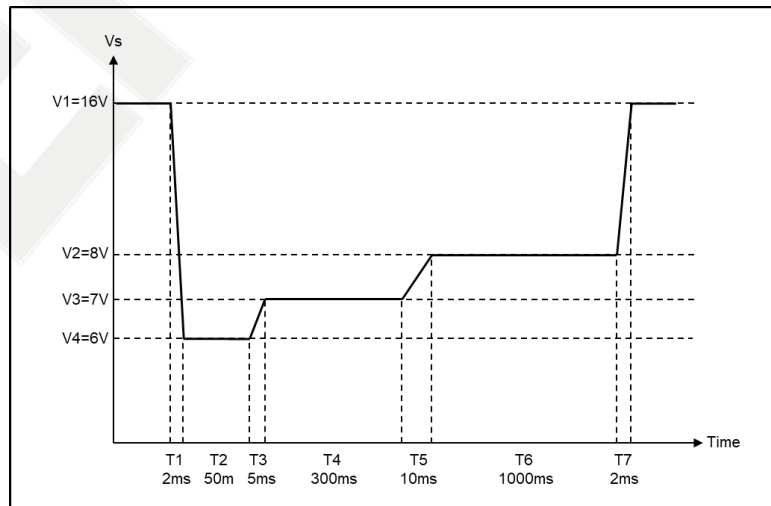

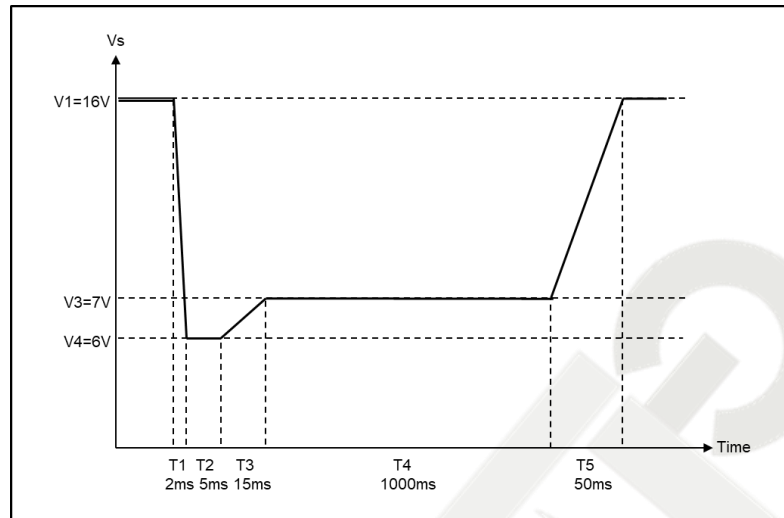

Figure 6 Battery cranking curve example 2

4.5.3 Advanced battery management (hybrid vehicles)

For sudden spikes in battery voltage, as in the case of Hybrid vehicles engine ignition, AXPA7851Q can handle such situations of 16V in 10ms spikes without any pop noise and interruptions.

Figure 7 Upwards fast battery transitions diagram

4.6 Output Clip Detection (CDOD)

The CDOD indicates Output Clip Detection during non Mute operation. It goes active low upon occurrence of clipping at the output waveform. An internal clipping circuit detects for output distortion of more than 1% and pulls down CDOD low. This acts as a feedback signal for the audio processor to reduce its output signal to the amplifier for clipping reduction. Clip detection is functional down to $V_s=6.5V$.

4.7 Output DC Offset Detection (CDOD)

The CDOD indicates Output DC Offset Detection during Mute operation.

To safeguard against damaging speakers because of large DC offsets at the outputs, an offset detector is designed into AXPA7851Q. When muted and without signal input, it detects for differential output voltage, to be within a threshold of $\pm 2V$ and pulls CDOD low if it is exceeded.

4.8 Protection

4.8.1 Short circuits

AXPA7851Q detects for short circuit under the conditions of:

1. Short to ground
When detected, the outputs are put into tristate high impedance. The device will only revert to normal operation when short is removed. This is determined by detecting the output voltage returning to internally set limits.
2. Short to V_s
When detected, the outputs are put into tri-state high impedance. The device will only revert to normal operation when the short is removed. This is determined by detecting the output voltage returning to internally set limits.
3. Short across the load
This is determined by sensing an over current at the outputs. The outputs are then put into a high impedance protection mode for $100\mu s$. The short is repeated checked every $100\mu s$. If the short is removed, the amplifier returns to normal operation, otherwise high impedance state is maintained.

4.8.2 Open circuit Operation

When there is an open load condition, no damage will occur. AXPA7851Q will continue to play.

4.8.3 Over-voltage and load dump

AXPA7851Q is designed to detect over voltage of beyond 19V. When detected, the amplifier outputs go into a high impedance state preventing damage. Normal play operations are reverted when V_s returns to the acceptable range.

The robustness of the design allows for protection against load dumps surges of as high as 50V with 5ms rise time and 50ms duration.

Figure 8 Load dump protection diagram

4.8.4 Thermal protection

Thermal warning is activated at T_j of 140°C. If T_j rise continues and reaches 150°C, a slow mute is then activated to reduce output power and dissipation. On reaching T_j of 170°C, the amplifier will be shutdown to prevent damage.

4.9 Heat sink definition

The power dissipation and temperature generated by the heat dissipation is governed by the following equation.

$$P_d * (R_{thj\sim case} + R_{thc\sim amb}) = T_j - T_a$$

P_d = Power dissipation of amplifier (W)

$R_{thj\sim case}$ = Thermal resistance from silicon junction to the package casing. (°C/W)

$R_{thc\sim amb}$ = Thermal resistance from case to ambient (°C/W)

T_j = Silicon junction operating temperature (°C)

T_{amb} = Ambient Temperature. (°C)

Example:

$P_d = 28W$

$R_{thj\sim case} = 1°C/W$

$T_j = 150°C$

$T_{amb} = 70°C$

$R_{thc\sim amb} = 1.8°C/W$

The heatsink need to be designed to have thermal resistance of 1.8°C/W or lower to avoid overheating and thermal shutdown.
